

dreamcontext — how two vaults federate

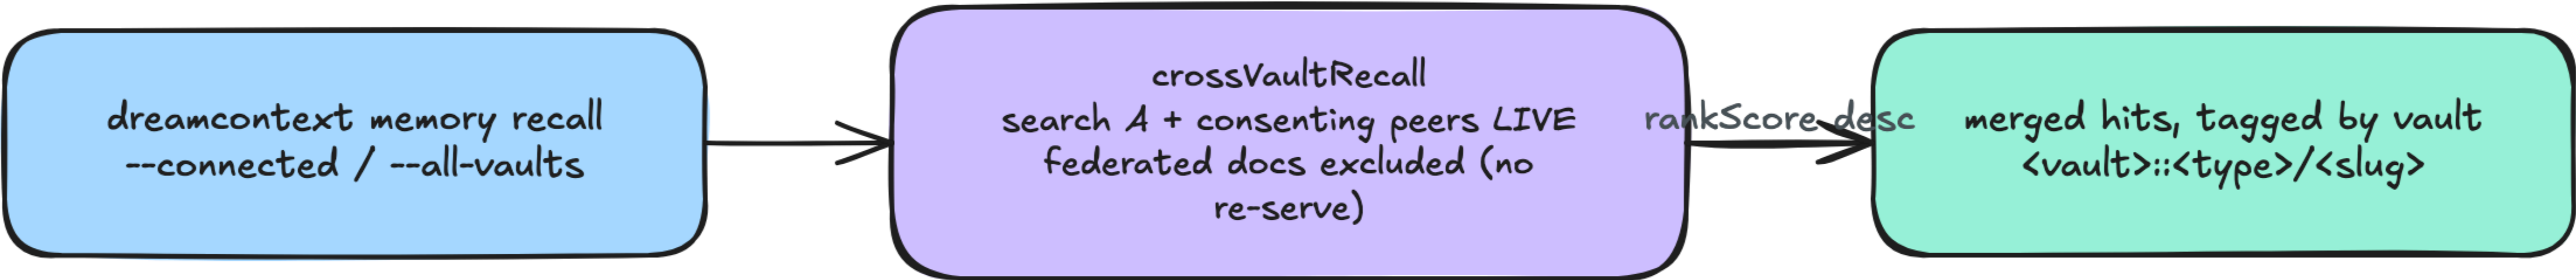

vault registry
(~/.dreamcontext)

Every _dream_context/ project addressable by name · the one shared index.

PUSH — sleep-driven, automatic

PULL — on-demand (you run it)

- There is no "when X, read Y" trigger.
- PUSH copies peer digests in at every sleep cycle → then they are just local.
- PULL is live but only when you pass --connected. The per-prompt hook is local-only.

The only knobs

- direction: out / in / both
- status: active / stale (dead peer skipped)
- consent: receiver shareable + reciprocal
- topics: filter WHAT (not WHEN)
